- Previously, we had shown that the zinc-dependent binding of certain fluorescent aryl sulfonamide inhibitors could be used with apocarbonic anhydrase II to transduce the level of free zinc as a change in the fluorescence of the inhibitor. While inhibitors such as dansylamide, ABD-M, and ABD-N made possible quantitation of free zinc in the picomolar range with high selectivity, they have only modest absorbance which limits their utility. We describe here the synthesis and properties of two new probes, Dapoxyl sulfonamide and BTCS, and their use in zinc biosensing. Dapoxyl sulfonamide exhibits a dramatic increase and blue shift in its emission upon binding to holocarbonic

anhydrase II, as well as a 20-fold increase in lifetime: it is thus well suited for **quantitating** free **Zn**(II) down to picomolar ranges. The anisotropy of BTCS increases fivefold upon binding to the **holoprotein**, making this probe well suited for anisotropy-based **detn**. of **zinc**. BTCS and ABD-N are efficiently excited with two photon excitation using 1.5 ps pulses from a titanium sapphire laser, and exhibit the increased zinc-dependent anisotropy response anticipated on the basis of photoselection.

- AB A new type of **fluorescence** transduction method for **detg**. **zinc** in soln. is described. The approach is based upon **energy transfer** from a **fluorescent** label on an enzyme, human carbonic anhydrase II, to a colored inhibitor which binds to zinc in the enzyme active site. If zinc is present in soln., it binds to the **apoenzyme**, which in turn permits the inhibitor to bind to the enzyme; the inhibitor is thus in close proximity to the label on the enzyme and thereby quenches the label's **fluorescence** by Forster **energy transfer** with a concomitant redn. of its lifetime, which is quantitated by phase fluorometry.
